**Abstract:** **Background:** Most commonly reported clinical manifestations are fever, fatigue and dry cough. Interestingly, a small percentage of patients experience GI symptoms, with the most common being anorexia, diarrhea, nausea and vomiting. We aimed to conduct a comparative study on COVID-19 patients with or without gastrointestinal patients (GI).

**Aims:** The pandemic of coronavirus disease 2019 (COVID-19) has emerged as a dire health problem, causing a massive crisis for global health.

**Methods:** Collective data of clinical manifestations and laboratory reports of patients admitted to Razi Hospital, Ahvaz, Khuzestan, Iran, for two weeks were analyzed.

**Results:** Our results showed that GI symptoms are not statistically significant criteria to be predictive or prognostic factors in COVID-19 patients, although they are probably related to the acute or non-acute phase of the disease. Moreover, non-specific GI symptoms seem to result from cytokine storm that occurred during the disease.

**Conclusion:** Therefore, our results did not support GI tract involvement as a common route of COVID-19 infection. Maybe future research will shed light on why and how the gastrointestinal system becomes infected by COVID-19.

**Keywords:** COVID-19, gastrointestinal, diabetes, cytokine, fever, digestive symptoms.

## 1. INTRODUCTION

The new coronavirus-caused respiratory disease known as coronavirus disease 2019 (COVID-19) spread through the world in December, 2019 [1, 2]. Among patients with COVID-19, the most significant risk factors are the patient's age and underlying diseases (particularly hypertension and diabetes). The manifestation of COVID-19 varies from asymptomatic to serious clinical complications, which involve multiple organs [3]. The most commonly affected organ is the pulmonary track manifesting respiratory symptoms, such as fever, cough, and shortness of breath. Although gastrointestinal (GI) signs, such as diarrhea, nausea, and vomiting [4, 5], neurological symptoms like cerebrovascular disease, impaired consciousness and muscle damage are also observed among COVID-19 patients [6, 7].

The presence of GI symptoms is considered to be of special significance in COVID-19-infected patients as they arise early and can worsen during disease progression [8-10]. According to an early study, the incidence of GI symptoms, such as diarrhoea, ranged from 1% to 3.8%. [11]. GI symptoms have also been noted to occur more frequently, with diarrhoea and nausea in 10.1% and vomiting in 3.6% of infected patients [12]. In the case of COVID-19 infection just by GI manifestation, it usually leads to a delay in diagnosis as well as a longer time to first respiratory symptoms, which can make patients a great source of viral dissemination. Thus, GI signs seem to be of special importance in COVID-19 [8]. In spite of the principal method for COVID-19 diagnosis, Reverse Transcriptase quantitative Polymerase Chain Reaction (RT-qPCR), on respiratory specimens [13], the virus is also detected in fecal [14], blood [15], and urine samples [16]. Chest CT scan is also sensitive for the diagnosis of COVID-19 and can be used as a primary tool [17].

Based on previous studies, high neutrophil count and increased levels of serum amyloid A (SAA), procalcitonin (PCT), C-reactive protein (CRP), cardiac troponin I (cTnI), D-Dimer, and lactate dehydrogenase (LDH) can be used as indicators of disease progression [7]. In addition, the viral nucleic acid has been detected in more than 50% of patients with COVID-19. Gastrointestinal symptoms may manifest due to infection of enterocytes expressing angiotensin-converting enzyme 2(ACE2), which is an entry receptor for the SARS-CoV-2 virus [18, 19]. Given that many SARS-CoV-2 infected patients may be detected solely based on respiratory symptoms, it is likely that patients without respiratory signs, especially those with gastrointestinal symptoms, will refer to medical centers later than other patients and have a delayed diagnosis [13]. This not only worsens the disease and results in poor prognosis but also enhances the probability of COVID-19 transmission. Therefore, in this study, we compare the clinical features and prognosis of COVID-19 patients with or without gastrointestinal symptoms in Razi Hospital in Ahvaz, Iran.

## 2. PATIENTS AND METHODS

### 2.1. Study Subjects

This retrospective descriptive, cross-sectional, and monocentric study involving 233 cases was conducted in Razi Hospital, Ahvaz, Iran, over a two-week period from April 27<sup>th</sup> to May 11<sup>th</sup>, 2021. The study included all patients with COVID-19 infection admitted to the hospital and confirmed by a real-time PCR on the nasopharyngeal swab, bronchoalveolar lavage, tracheal aspirate and oral or stomach swab. Clinical manifestations and laboratory reports were documented. Patients who did not meet the inclusion criteria were excluded from the study. Then, the consequences of each individual were followed.

### 2.2. Variables

We accumulated the information of patients regarding demographic data (such as age, gender, and smoking status), comorbidities (history of hypertension, diabetes, dyslipidemia, coronary artery disease, chronic obstructive pulmonary disease, and asthma), clinical characteristics including digestive symptoms (anorexia, nausea/vomiting, diarrhea, or abdominal pain), and other symptoms (fever, cough, expectoration, and dyspnea) at the time of discharge or deceased.

### 2.3. Ethical Issues

This study was approved by the Ethics Committee of Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran (IR.AJUMS.REC.1399.276). Details of the plan were described for all participants, and written consent was signed by individuals.

### 2.4. Statistical Analysis

The random survival forest technique was utilized to assess the impact of various variables at the time of death/discharge and time interval from admission to ICU. In this dataset, dying from COVID-19 and ICU hospitalization were

considered as the events. Moreover, discharge and not being hospitalized in ICU were assumed as the right censoring. When the number of covariates and factors far exceeds the number of observations, routine and standard survival analysis approaches, such as Cox's proportional hazard regression, do not result in adequate and reliable estimations [20].

To compare continuous variables of two groups (discharged and deceased), independent samples t-test was used. The independence between categorical variables and the outcome was checked by the chi-square or Fisher's exact test. To visualize the development of survival probabilities for the categories of gastrointestinal and respiratory symptoms, Kaplan-Meyer curves were plotted. Moreover, the log-rank test was used to investigate the different levels of gastrointestinal and respiratory symptoms in terms of survival probabilities. To evaluate the unadjusted effects of gastrointestinal and respiratory symptoms presence/absence, odds ratio (95% confidence interval) estimates were reported in different levels of death/discharge variable.

## 3. RESULTS

Demographic data showed that out of 233 cases of COVID-19, 122 patients were men and 111 were women. Moreover, 44 patients (18.9%) died, and 188 individuals (81.1%) were discharged after recovery. It was observed that 39 cases (16.7%) were ICU admitted. The distribution of variables across the two groups of the deceased and the discharged is shown in Table 1. The odds ratio of death from COVID-19 was 4.78 times more among ICU cases than those who were not ICU-admitted.

It was shown that the presence of respiratory and gastrointestinal symptoms is not statistically associated with mortality. In contrast to the O<sub>2</sub> index, the mean of respiratory rate, age, aspartate aminotransferase (AST), AST/alanine aminotransferase (ALT), direct bilirubin, blood urea nitrogen (BUN), LDH, neutrophil, prothrombin time (PT), international normalized ratio (INR), and C-Reactive Protein (CRP) were significantly higher among group dying from COVID-19. Among ICU-admitted cases, the proportion between death and discharged patients were 17 (43.58%) and 22 (56.41%), respectively.

The distribution of presence/absence of respiratory and gastrointestinal symptoms among two groups of death/discharged individuals is shown in Tables 2 and 3. The time of admission to death/discharged and the respiratory rate were lower among those without respiratory symptoms; however, a similar comparison was statistically significant in cases who were discharged. Among the discharged cases, the mean values of BUN ( $p = 0.019$ ) and blood platelet (PLT) ( $p=0.019$ ) were significantly lower and higher, respectively, in the positive respiratory symptoms group. In the deceased group, the mean value of phosphate (P) and creatine kinase (CK)-MB were respectively higher and lower for those without respiratory symptoms. The mean value of blood sugar (BS) and potassium (K) were significantly higher among those with gastrointestinal symptoms for both deceased and discharged cases.

**Table 1.** The distribution of variables across the two groups of dead and discharged patients.

The Kaplan-Meyer curve for respiratory and gastrointestinal symptoms is shown in Fig. 1. The survival rate of cases with and without respiratory symptoms was  $18.25 \pm 1.24$  days and  $17.27 \pm 1.25$  days, respectively. The log-rank test showed no statistical difference in the survival curve of the two groups (log-rank = 0.315, *p*-value = 0.575). The survival rate of individuals with and without gastrointestinal symptoms was  $15.34 \pm 0.55$  and  $18.51 \pm 1.35$ , respectively, and the log-rank test showed no difference in the survival curve of the two groups (log-rank = 0.063, *p*-value = 0.801).

The results of random survival forest are shown in Figs. (2 and 3) so that the order of most significant variables can be presented. As shown in Fig. (2), the most significant variables affecting death/discharged patients due to COVID-19 were partial thromboplastin time (PTT), respiratory rate, neutrophil, surgery, direct bilirubin, hematocrit (HCT), phosphorus (P), AST/ALT, age, and Parkinson's disease, respectively. However, the most significant factors affecting ICU admission followed by COVID-19 were respiratory rate, O<sub>2</sub> index, breast cancer, lymphocytes, once admission, CRP, neutrophil, pulmonary thromboendarterectomy (PTE), LDH, and AST/ALT.

#### 4. DISCUSSION

COVID-19 infection manifests a wide spectrum of signs according to various studies since the disease outbreak [3-6]. GI symptoms are one of special significance in COVID-19 patients as, in contrast to other coronaviruses, they appear sooner and may worsen the symptoms of the infection [10]. Patients who manifest only GI symptoms might be followed

by respiratory symptoms and with a delay in disease diagnosis. This can make patients a blurred source of viral dissemination [8]. In our study, we first compared some important variables between the two groups of patients who were discharged or deceased after a while. Our results indicated an 18.9% mortality rate for COVID-19 and a 1:4.2 mortality/discharge ratio in COVID-19 patients, which was close to some studies [21] but higher than some others [22]. This may be justified by a hypothesis that different variants of coronavirus can affect individuals living in different countries; therefore, various outcomes may have occurred following COVID-19 infection.

In our study, not only the rate of O<sub>2</sub> index, the mean respiratory rate, and the age of patients, but also the rates of laboratory findings, including AST, AST/ALT, direct bilirubin, BUN, LDH, neutrophil, PT, INR, and CRP values were significantly higher among the deceased group due to COVID-19. Similar results have also been shown in many other studies [23-31]. Some of these criteria belong to the acute phase of infection, and some others change over time; thus, they could be considered predictors of chronic inflammation. Accordingly, it can be hypothesized that COVID-19 is potentially a subclinical chronic disease triggering an inflammation storm and leading to enhanced mortality. Based on previous studies [32-36], our analyzed data showed lower BUN and higher PLT among discharged cases which can be considered suitable prognostic factors. The platelet count may support the non-acute phase of the COVID-19 disease. Also, the phosphorus and CK-MB levels in patients without respiratory symptoms were consistent with the previous literature [37-40].

**Table 2.** The distribution of presence/absence of respiratory symptoms in two levels of death/discharged patients.

**Fig. (1).** Kaplan-Meier curve for survival probabilities of respiratory and gastrointestinal symptoms. (A higher resolution/colour version of this figure is available in the electronic copy of the article).

**Fig. (2).** The importance of factors affecting death/discharged patients due to COVID-19. (A higher resolution/colour version of this figure is available in the electronic copy of the article).

**Fig. (3).** The importance of variables affecting ICU admission followed by COVID-19. (A higher resolution/colour version of this figure is available in the electronic copy of the article).

Furthermore, we compared the clinical characteristics of COVID-19 patients with and without gastrointestinal symptoms. The values of BS and potassium were significantly higher in all patients with GI symptoms [41-43], although diabetes mellitus is considered to be a risk factor for mortality in COVID-19 patients [44-46]. Moreover, there was no significant difference in the survival curve of patients with or without GI symptoms, and respiratory signs speculating neither GI nor respiratory manifestations did not affect the survival of COVID-19 patients. On the contrary, other studies with a higher sample size reported that respiratory symptoms are associated with survival rate in COVID-19 patients [29, 47, 48]. Moreover, the most important variables affecting mortality were O<sub>2</sub> index, anemia, white blood cells (WBC), LDH, INR, PT, erythrocyte sedimentation rate (ESR), PTT, respiratory rate, neutrophil, and direct bilirubin. This evidence depicted that respiratory hallmarks potentially influence survival rate, which was contrary to the results found in other

studies. Hence, further research works are necessary to justify this discrepancy.

Previously, two large clinical studies from China focused on GI symptoms [49-52]. In the study conducted by Jin *et al.*, a total of 74 patients infected with SARS-CoV-2 manifested GI symptoms, such as diarrhoea, nausea, and vomiting. Interestingly, up to 28% of those patients with GI symptoms did not manifest respiratory symptoms [49]. They demonstrated that these patients, compared to those without GI symptoms, had overall more severe/critical disease, and more individuals were reported to have fever >38.5 °C and family clustering and higher rates of liver injury following assessment by elevated AST levels [49].

## CONCLUSION

Gastrointestinal symptoms are not found to be associated with the longevity rate of COVID-19 patients, suggesting that

they are probably not recognized as a suitable prognostic factor. However, our findings regarding the relationship between respiratory signs and survival rate were controversial may be due to the small size of under-studied patients. Interestingly, some serum criteria, including lower BUN and higher PLT, can be considered promising prognostic factors in COVID-19 and others, such as platelet count, may support the non-acute phase of the COVID-19 disease.

## LIST OF ABBREVIATIONS

|          |   |  |

## ETHICS APPROVAL AND CONSENT TO PARTICIPATE

This study was approved by the Ethics Committee of Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran (IR.AJUMS.REC.1399.276). The purpose of the study was described to all patients, and written consent was obtained from them.

## HUMAN AND ANIMAL RIGHTS

No animals were used in the study. All human procedures were performed in accordance with the ethical principles for medical research involving human subjects by the World Medical Association Declaration of Helsinki.

## STANDARDS OF REPORTING

STROBE guidelines were followed.

## CONSENT FOR PUBLICATION

The authors declare to follow all the protocols concerning the publication of patient data and that all the patients included in the study have received sufficient information and have given their informed consent in writing to participate in the study.

## AVAILABILITY OF DATA AND MATERIALS

The datasets used and/or analyzed during the current study are available from the corresponding author upon reasonable request.

## FUNDING

This work was financially supported by the vice chancellor for the Ahvaz Jundishapur University of Medical Sciences' research affairs (Grant No.: U-99093) Iran.

## CONFLICT OF INTEREST

The authors declare no conflict of interest, financial or otherwise.

## ACKNOWLEDGEMENTS

The authors would like to acknowledge the support from the Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran.
